# Analytic white-box performance models

An analytic white-box performance model is a simplified mathematical description of the hardware and its interaction with software. It is able to predict the runtime/performance of code from "first principles."

# A simple performance model for loops

#### Simplistic view of the hardware:

Simplistic view of the software:

```
! may be multiple levels
do i = 1,<sufficient>
        <complicated stuff doing
        N flops causing
        V bytes of data transfer>
enddo
```

Computational intensity  $I = \frac{N}{V}$ The intensity  $I = \frac{N}{V}$ Unit: flop/byte

### Naïve Roofline Model

How fast can tasks be processed? *P* [flop/s]

#### The bottleneck is either

• The execution of work:  $P_{\text{peak}}$ 

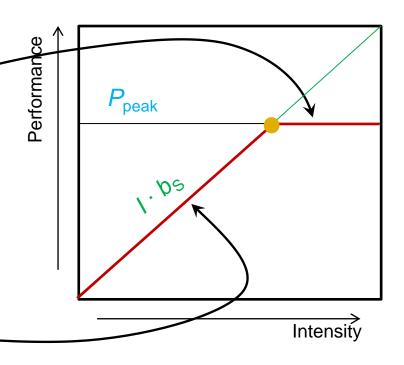

■ The data path:  $I \cdot b_S$  [flop/byte x byte/s]

[flop/s]

 $P = \min(P_{\text{peak}}, I \cdot b_S)$ 

This is the "Naïve Roofline Model"

- High intensity: P limited by execution
- Low intensity: P limited by data transfer
- "Knee" at  $P_{peak} = I \cdot b_S$ : Best use of resources
- Roofline is an "optimistic" model (think "light speed")

# The Roofline Model in computing – Basics

#### Apply the naive Roofline model in practice

Machine parameter #1:

Peak performance:

 $P_{peak} \left[ \frac{F}{s} \right]$ 

Machine model

Machine parameter #2:

Memory bandwidth:

 $b_S\left[\frac{B}{s}\right]$ 

Application model

Code characteristic:

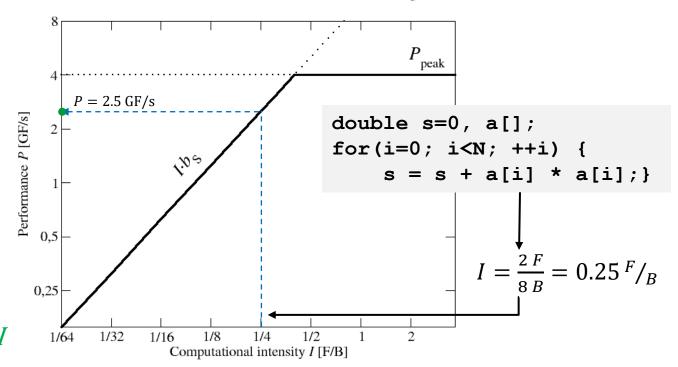

Computational intensity: I

Machine properties:

$$P_{peak} = 4 \frac{GF}{S}$$

$$b_S = 10 \frac{\text{GB}}{\text{S}}$$

Application property: I

# Prerequisites for the Roofline Model

- Data transfer and core execution overlap perfectly!
  - Either the limit is core execution or it is data transfer

- Slowest limiting factor "wins"; all others are assumed to have no impact
  - If two bottlenecks are "close," no interaction is assumed
- Data access latency is ignored, i.e. perfect streaming mode
  - Achievable bandwidth is the limit
- Chip must be able to saturate the bandwidth bottleneck(s)
  - Always model the full chip

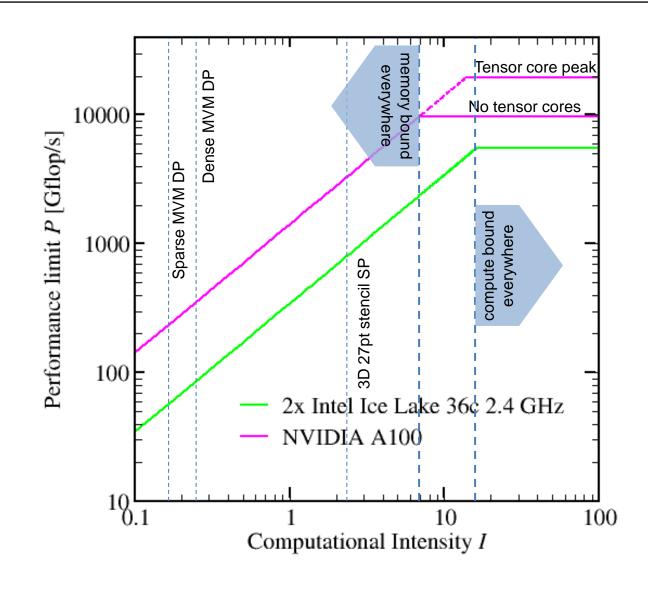

### Roofline for architecture and code comparison

#### With Roofline, we can

- Compare capabilities of different machines
- Compare performance expectations for different loops

- Roofline always provides upper bound but is it realistic?
  - Simple case: Loop kernel has loop-carried dependencies → cannot achieve peak
  - Other bandwidth bottlenecks may apply

[Byte/s]

- 1.  $P_{\text{max}}$  = Applicable peak performance of a loop, assuming that data comes from the level 1 cache (this is not necessarily  $P_{\text{peak}}$ )
  - $\rightarrow$  e.g.,  $P_{\text{max}} = 176 \text{ GFlop/s}$
- 2.  $b_S$  = Applicable (saturated) peak bandwidth of the slowest data path utilized  $\rightarrow$  e.g.,  $b_S$  = 56 GByte/s
- 3.  $I = \text{Computational intensity ("work" per byte transferred) over the slowest data path utilized (code balance <math>B_C = I^{-1}$ )
  - $\rightarrow$  e.g., I = 0.167 Flop/Byte  $\rightarrow B_C = 6$  Byte/Flop

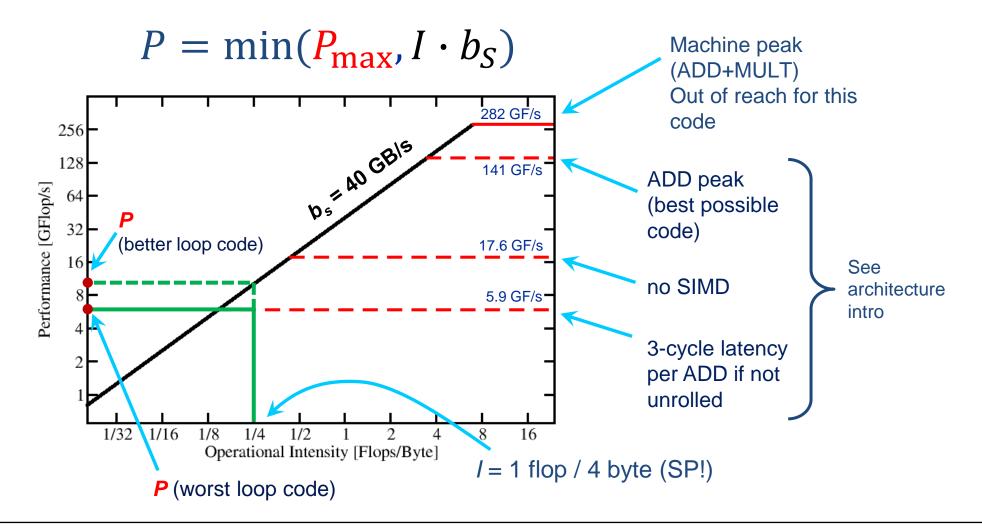

$$P = \min(P_{\text{max}}, I \cdot b_S) = \min\left(P_{\text{max}}, \frac{b_S}{B_C}\right)$$
[Byte/Flop]

Roofline Model (c) NHR@FAU 2024

#### Full Roofline for the sum reduction from the intro

Example: do i=1,N; s=s+a(i); enddo

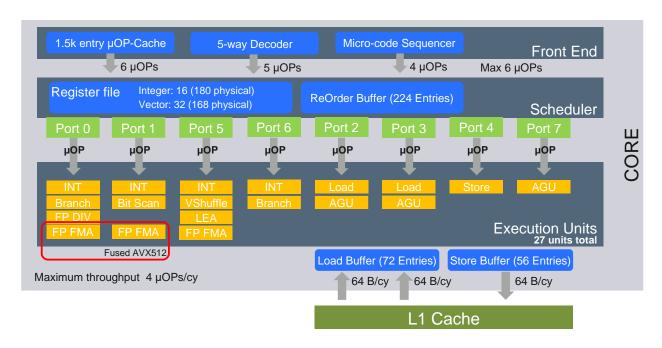

in single precision on an 8-core 2.2 GHz Sandy Bridge socket @ "large" N

### Complexities of in-core execution $(P_{\text{max}})$

#### Multiple bottlenecks:

- Decode/retirement throughput
- Port contention (direct or indirect)
- Arithmetic pipeline stalls (dependencies)
- Overall pipeline stalls (branching)
- L1 Dcache bandwidth (LD/ST throughput)
- Scalar vs. SIMD execution
- L1 Icache (LD/ST) bandwidth
- Alignment issues
- ...

Skylake

### Code balance: more examples

```
double a[], b[];
for(i=0; i<N; ++i)
    a[i] = a[i] + b[i];
double a[], b[];
for(i=0; i<N; ++i)
    a[i] = a[i] + (s) * b[i];
float s=0, a[];
for(i=0; i<N; ++i)
    s = (s) + a[i] * a[i];
float s=0, a[], b[];
for(i=0; i<N; ++i)
    s = (s) + a[i] * b[i];
```

```
B_{\rm C} = 24B / 1F = 24 B/F
I = 0.042 F/B
```

$$B_{\rm C} = 24$$
B / 2F = 12 B/F  
 $I = 0.083$  F/B

➤ Scalar – can be kept in register

$$B_{\rm C} = 4B / 2F = 2 B/F$$
  
 $I = 0.5 F/B$ 

Scalar – can be kept in register

$$B_{\rm C} = 8B / 2F = 4 B/F$$
  
 $I = 0.25 F/B$ 

Scalar – can be kept in register

```
B_{\rm C} = 16 \, \text{B} / 2 \, \text{F} \text{ or}
8B / 2F or even ???
20 B / 2F
```

Streaming, perfect spatial locality, no temporal locality  $\rightarrow$  simple

And what about this?

```
float s=0, a[], b[];
int idx[];
for(i=0; i<N; ++i)
    s = s + a[i]
    * b[idx[i]];</pre>
```

Possible cache reuse → tricky!

We'll get to it!

# Is there anything to ease the construction of the model?

### Code balance $B_C$

- Close inspection and hard thinking
- Simplifying assumptions
  - "What is the minimum possible amount of traffic?"
  - "What is the worst case?"

- Tools
  - Kerncraft https://github.com/RRZE-HPC/kerncraft

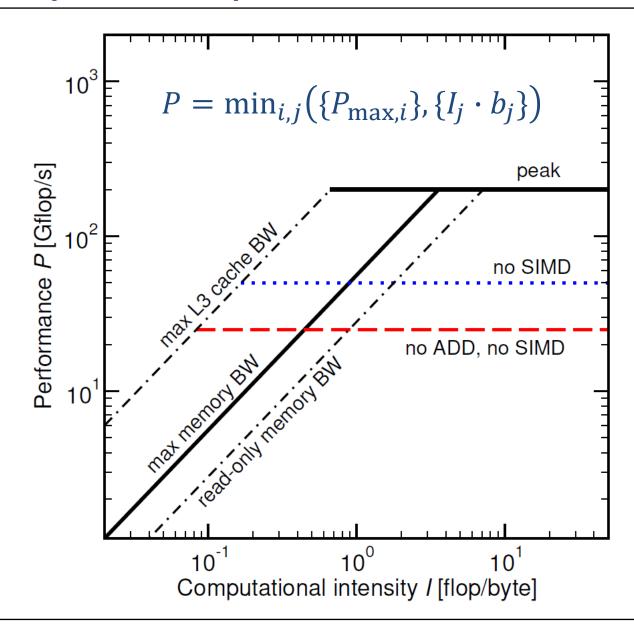

### In-core $P_{\text{max}}$

- Inspection of assembly code and manual modeling
- Simplifying assumptions
  - "What is the required minimum number of arithmetic/load/store instructions?"
  - $P_{\text{max}} = P_{peak}$
- Tools
  - OSACA <u>https://github.com/RRZE-HPC/OSACA</u>

# Refined Roofline model: graphical representation

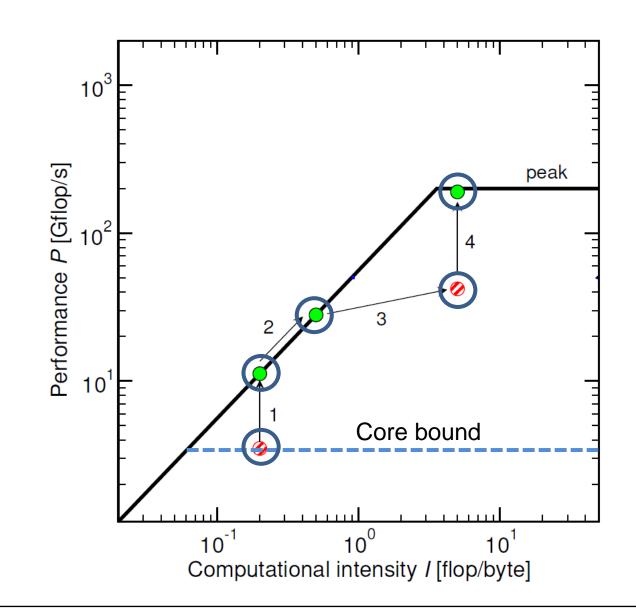

### Multiple ceilings may apply

- Different bandwidths / data paths
  - → different inclined ceilings
  - → possibly different *I* for one kernel
- Different P<sub>max</sub>
   → different flat ceilings
  - In fact,  $P_{\text{max}}$  should always come from code analysis; generic ceilings are usually impossible to attain

### Tracking code optimizations in the Roofline Model

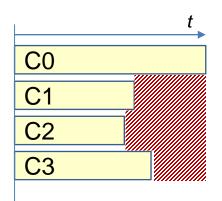

- Hit the BW bottleneck by good serial code
   (e.g., Ninja C++ → Fortran)
- 2. Increase intensity to make better use of BW bottleneck (e.g., spatial loop blocking)
- 3. Increase intensity and go from memory bound to core bound (e.g., temporal blocking)
- 4. Hit the core bottleneck by good serial code (e.g., -fno-alias, SIMD intrinsics)

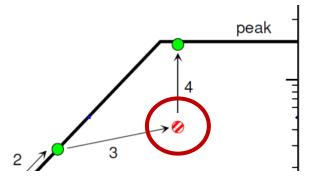

### Roofline: How can it "fail"?

... assuming that you did the math right?

- Load imbalance
  - May be impossible to saturate memory bandwidth
  - This includes serial code
- "Slow code"
  - "Invisible" performance ceiling due to inefficient instructions or inefficient execution

- Erratic memory access patterns
  - Latency rains on your parade

```
for(int i=0; i<N; ++i)
  a[i] = s * b[index[i]];</pre>
```

# Diagnostic / phenomenological Roofline modeling

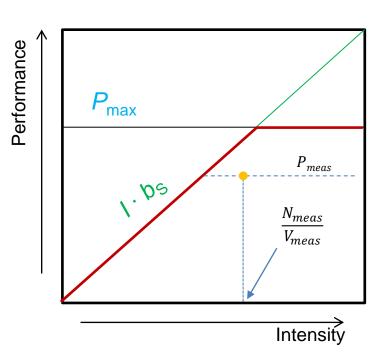

# Diagnostic modeling

- What if we cannot predict the intensity/balance?
  - Code very complicated
  - Code not available
  - Parameters unknown
  - Doubts about correctness of analysis
- Measure data volume  $V_{meas}$  (and work  $N_{meas}$ )
  - Hardware performance counters
  - Tools: likwid-perfctr, PAPI, Intel Vtune,...

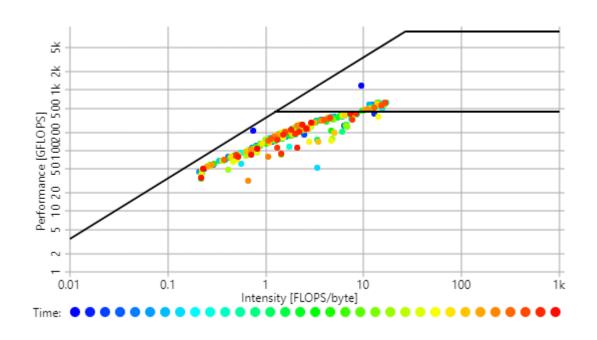

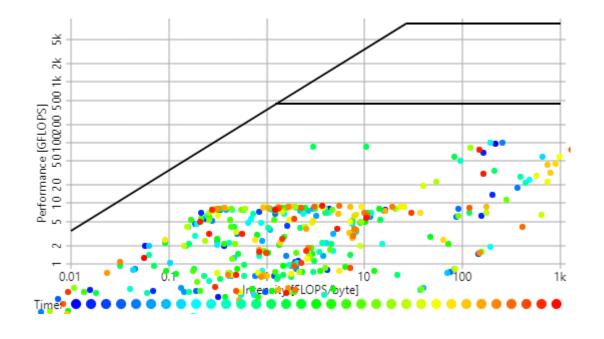

- Compare analytic model and measurement → validate model
- Can be applied (semi-)automatically
- Useful in performance monitoring of user jobs on clusters

# Roofline and performance monitoring of clusters

### Two cluster jobs...

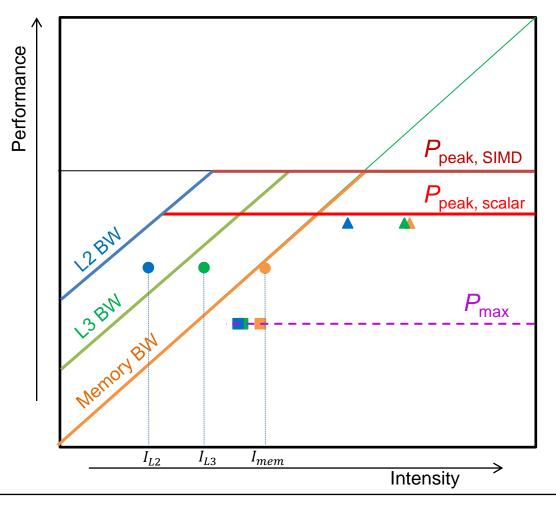

Which of them is "good" and which is "bad"?

# Diagnostic modeling of a complex code (3 kernels)

Multiple bandwidth bottlenecks

 $\rightarrow$  need I for each one  $(I_{mem}, I_{L3}, I_{L2}, ...)$ 

#### Kernel 1

- Performance close to memory BW ceiling but far away from others
  - → indicates memory bound

#### Kernel 2

- Performance not near any BW ceiling
- Performance close to scalar peak ceiling
  - → indicates scalar core-bound peak code

#### Kernel 3

- Performance not anywhere near any ceiling
  - $\rightarrow$  There must be an (as yet) unknown in-core performance limit  $P_{\text{max}}$

### Roofline conclusion

- Roofline = simple first-principle model for upper performance limit of datastreaming loops
  - Machine model  $(P_{max}, b_S,...)$  + application model  $(I_{mem},...)$
  - Conditions apply, extensions exist
- Two modes of operation; per kernel:
  - Predictive: Calculate  $I_j$ , calculate upper limit, validate model, optimize, iterate
  - Diagnostic: Measure  $I_i$  and P, compare with ceilings
- Challenge of predictive modeling: Getting  $P_{max}$  and I right
