

PTfS-CAM

Project: Modelling 2D steady-state heat equation

Part 2

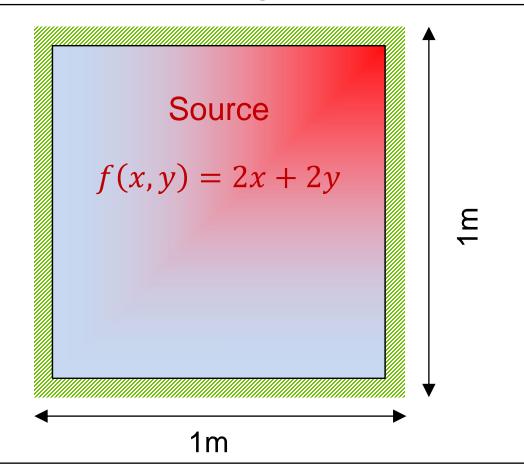

Overview

- Recap from part 1
- Discuss new tasks
- Roofline Model example

Scenario: Heat dissipation on a rectangular plate

Find steady state temperature distribution inside the plate!

Boundary
$$T(\varphi) = 0$$

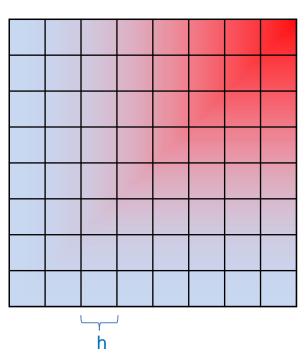

Discretization

$$-\Delta u = -\left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2}\right) = f$$

Use Finite Difference Method (FDM) for discretization

$$\Rightarrow -\Delta u = -\left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2}\right) (x, y) \approx$$

$$\frac{1}{h^2} (4u(x,y) - u(x-h,y) - u(x+h,y) - u(x,y-h) - u(x,y+h))$$

Solving linear system

Solve for
$$u : -\Delta u = f$$

- 1. Use Conjugate Gradient (CG)
- 2. Use Preconditioned Conjugate Gradient (PCG) with symmetric Gauss-Seidel preconditioning

PTfS-CAM project part 2 04/07/2024

Your tasks

- 1. Clone the code from Github: git clone https://github.com/RRZE-HPC/PTfS-CAM-Project.git
- 2. Build the code using the given Makefile, i.e., just type CXX=icpx make
- 3. To switch on LIKWID measurement (for part 2) set the LIKWID flag to 'on', i.e., LIKWID=on CXX=icpx make
- 4. Check for code correctness using the **test** executable: ./test
- 5. To run the actual code, use the **perf** executable:

 ./perf num_grids_y num_grids_x
- 6. If all tests pass, parallelize building blocks using OpenMP. Always observe correctness!
- 7. Are there any possible performance optimizations that you could do in the CG and PCG solver implemented in SolverClass:: (P) CG (Solver.cpp)? If so, implement them!

Your tasks (new)

- 8. Calculate roofline predictions in [LUP/s] for CG and PCG on 1 ccNUMA domain (18 cores) of Fritz. Calculate for three grid sizes : 2000×20000 , 20000×2000 and 1000×400000 . The last dimension is in x-direction (innermost). Does the performance change? Why?
- 9. Check whether you attain the roofline performance by running the code on 1 ccNUMA domain of Fritz for the three dimensions given above. Timings are already included. Run the code using following command.

```
<OMP_stuff> ./perf num_grids_y num_grids_x
```

- 10. Measure the code balance in [bytes/LUP] of 'applyStencil' and 'GSPreCon' kernels on 1 ccNUMA domain (18 threads) for the three grid dimensions and comment whether it agrees with your model. You can use LIKWID for the measurement.
 - To switch on LIKWID measurement set the LIKWID flag to 'on', i.e.,
 LIKWID=on CXX=icpx make
- 11. How does the CG and PCG code scale from 1 ccNUMA domain to 1 node (4 ccNUMA domains, 72 cores) of Fritz? Does it scale perfectly? If not, why? Can you fix it?

PTfS-CAM project part 2

Performance prediction for entire algorithm

PCG example

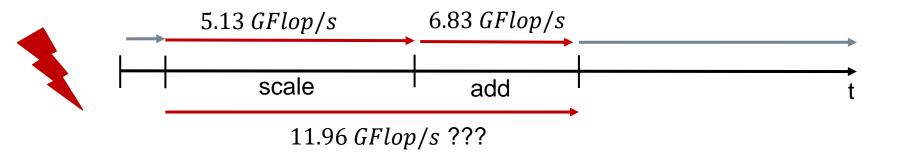

```
while( (iter<niter) && (res norm > tol*tol) )
              = A p
                 <v,p>
              = x + \lambda p
                                               Multiple kernels
              = Pr
         \alpha 1 = \langle r, z \rangle
         \alpha 0 = \alpha 1
         ++ iter
```

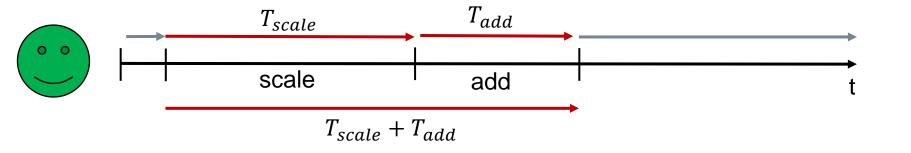

Performance prediction for entire algorithm: example

```
void scale(int n,...)
    for(int i=0; i<n; ++i)</pre>
         a[i] = c*b[i];
                       Not
                       considering
void add(int n,...)
                       write-allocates
    for (int i=0; i < n; ++i)
         a[i] = b[i] + d*c[i];
int main()
    scale(1e8,...);
    add(1e8,...);
    return 0;
```

```
I_{\text{scale}} = \frac{1}{16} \frac{Flop}{Byte}, \quad P_{\text{scale}}^{\text{max}} = 1 \times 8 \times 2 \times 18 = 288 \ GFlop/s
                              ST SIMD f
                                                         #cores
P_{\text{scale}} = \min(288, 82/16) = 5.13 \, GFlop/s
I_{add} = \frac{2}{24} \frac{Flop}{Byte}, P_{add}^{max} = 2 * 8 * 2 * 18 = 576 GFlop/s
P_{add} = min(576, 82*2/24) = 6.83 \, GFlop/s
Is it P_{total} = P_{scale} + P_{add}?
```

Performance prediction for entire algorithm: example

PTfS-CAM project part 2 04/07/2024

10

Performance prediction for entire algorithm: example

```
void scale(int n,...)
    for(int i=0; i < n; ++i)
        a[i] = c*b[i];
void add(int n,...)
    for(int i=0; i<n; ++i)</pre>
        a[i] = b[i] + d*c[i];
int main()
    scale(1e8,...);
    add(1e8,...);
    return 0;
```

```
I_{\text{scale}} = \frac{1}{16} \frac{Flop}{Byte}, \ P_{\text{scale}}^{\text{max}} = 1 \times 8 \times 2 \times 18 = 288 \ GFlop/s
                                     SIMD f
                                                           #cores
P_{\text{scale}} = \min(288, 82/16) = 5.13 \, GFlop/s
I_{add} = \frac{2}{24} \frac{Flop}{Byte}, P_{add}^{max} = 2 * 8 * 2 * 18 = 576 GFlop/s
P_{add} = min(576, 82*2/24) = 6.83 \, GFlop/s
Is it P_{total} = P_{scale} + P_{add}? NO
But T_{total} = T_{scale} + T_{add}
                                                            A more useful
T_{\text{total}} = \frac{1e8*1 \, Flop}{P_{\text{scale}}} + \frac{1e8*2 \, Flop}{P_{\text{add}}} = 0.0487 measure of
                                                            performance
=> P_{\text{total}} = \frac{1e8 \, It}{T_{\text{total}}} = 2.05 \, GIT/s^{2}
                                                            here
```

Things to take care

- Think to use loop fusion wherever necessary.
- For debugging please compile code as: CXX=icpx make EXTRA_FLAGS=-DDEBUG
- Sometimes it's useful for debugging to visualize your arrays. Use the function writeGnuplotFile and plot using splot in gnuplot if needed.
- Take particular care with parallelizing the Gauss-Seidel preconditioner.
- Use Fritz (Ice Lake) for getting your performance results.
- Fix clock frequency to 2.0 GHz (and use performance governor)
- Check if the measurements are reproducible. (Think of pinning, scheduling, and clock frequency).
- Request a dedicated node for measuring performance.

PTfS-CAM project part 2

Things to take care

- Remember pinning (-C with likwid-perfctr) when doing performance counter measurements. Use -m for using markers, instead of end-to-end measurement.
- When measuring parallel loops with likwid-perfctr, LIKWID_MARKER_START and LIKWID_MARKER_STOP should be called by all threads.
- Remember likwid-perfctr can incur some overheads, so for performance measurement better run without likwid-perfctr.
- Remember to arrive at final roofline model of (P)CG, you would need to stitch performance models of different kernels. It might be convenient to use a time-based model (see previous slides). If you wish use Excel sheet for this.
- For roofline modeling you can assume the memory bandwidth of 1 ccNUMA domain of Fritz is 82 GB/s.
- Remember Fritz has a write-allocate avoiding mechanism that can kick in some cases.

PTfS-CAM project part 2

Submission

- Submit the code after doing tasks using the link in PTfS Moodle. Please compress and submit only a single (ZIP) file. Include code and the report in submission.
- Deadline is 1 week before your oral exam.
- The report should contain all the details necessary to reproduce your measurements.
- All submitted code should be compilable by just typing make (Makefile is already provided),
- Your code should pass all the tests.
- Both executables (test and perf) should run without segmentation faults.
- While submitting report expected roofline performance and the measured performance, use $\left[\frac{LUP}{s}\right]$ (= $\left[\frac{IT}{s}\right]$) as performance metric, see definition in perf.cpp.
- If there is any substantial deviation between these values, please explain plausible cause if any.

Final remark

 In the exam you will be definitely asked questions based on this exercise.

Happy Coding !!!
